**ABSTRACT**

In this paper, we describe the Radio Aurora Explorer (RAX) and its space weather mission. RAX is a satellite mission funded by the National Science Foundation (NSF) to study space weather, and is a joint effort between SRI International and the University of Michigan and. The primary mission objective is to study plasma instabilities that lead to magnetic field-aligned irregularities (FAI) of electron density in the lower polar thermosphere (80-300 km). These irregularities are known to disrupt communication and navigation signals. The RAX mission will use a network of existing ground radars that will scatter signals off the FAI to be measured by a receiver on the RAX spacecraft. The satellite is a 3kg Cubesat with a scheduled launch date of May 28, 2010. RAX is the first of the NSF-sponsored satellites to be manifested for a launch and represents a path forging activity for similar science missions conducted on nanosatellite vehicles.

**INTRODUCTION**

The Radio Aurora Explorer (RAX) is the first of several nanosatellites commissioned by the National Science Foundation (NSF) to study and extend our knowledge of space weather. In 2008, NSF hosted a workshop to explore the potential use of a specific nanosatellite form factor, the Cubesat [1], for novel space weather missions. Despite their obvious limitations in mass (less than 4kg) and size (less than 10x10x30cm ) these small satellites offer potential advantages that compliment their larger forerunners. They provide the opportunity for fast implementation and

deployment of sensors in space; for focused and narrow science missions that target a specific space weather phenomenon; and for increased multi point measurements of space processes through coordinated and distribute satellites. Also, due to their low-cost, missions that are creative, and higher-risk are acceptable and encouraged [2]. Proposals to the NSF program included science missions to investigate upper-atmospheric, ionospheric, magnetospheric, and solar space weather research. Currently, the NSF funds six missions. RAX is the first of these missions with a scheduled launch in late 2010.

The RAX space weather investigation seeks to better understand the distribution and genesis of naturally occurring ionospheric irregularities by deploying a first-ever ground-to-space bistatic coherent-scatter radar system. Plasma irregularities are naturally occurring ionospheric structures that can significantly degrade the performance of satellite-based communication and navigation systems. As our economy and society becomes increasingly dependent on GPS and space-based communication, commerce and human safety can be threatened by even momentary system outages.

The RAX mission overcomes the limitations of existing measurements by using a novel ground-to-space bi-static radar experimental configuration. The ground-to-space bi-static geometry enables high horizontal and altitudinal resolution measurements of the auroral FAI. The high resolution is achieved through two factors: (1) the radar illuminating the irregularities has a narrow beam width, which is typical of all incoherent scatter radars (ISR), and (2) the radar-to-irregularity distance is short because the radar can be pointed at high elevation angles (as opposed to a monostatic radar pointed at very low elevation to meet the perpendicularity condition).

Beyond science and technology, RAX has a strong commitment to post-secondary and K-12 outreach. The RAX PIs hope to create a new class of opportunities for *student space physics experimentalists* by inviting graduate and undergraduate students to participate in a series of orbital radar experiment workshops, a once-in-an-academic-lifetime opportunity to influence mission science execution. Through fabrication, testing, operations, analysis, and discovery, the RAX mission will also involve as many as 200 students, providing them with a broad skill set of engineering design, project management, scientific analysis, and community outreach. The RAX mission has

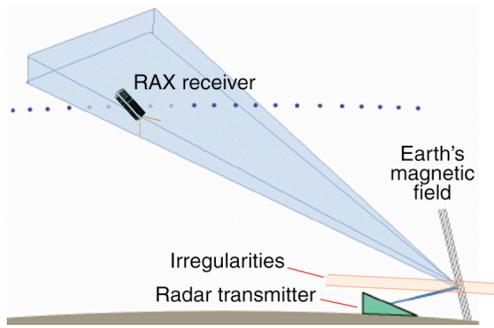

already engaged K-12 students in high-altitude balloon field tests of critical RAX position and timing subsystems. By selection of telemetry in the 70 cm amateur radio band and widespread propagation of modulation formats, RAX will engage a global community in tracking health, status, and science data streams on-orbit.

In the rest of this paper, we provide an overview of the RAX mission. We summarize the scientific background and objectives, and describe our scientific method for measurements. We then discuss the RAX satellite design and conclude with a summary of mission status.

## SCIENCE OVERVIEW

RAX is a plasma-sensing UHF radar mission developed in response to NSF's 2008 CubeSat-based Science Missions for Space Weather and Atmospheric Research. The RAX mission goals are to better understand the genesis and distribution of naturally occurring ionospheric irregularities—a space weather phenomenon that can severely degrade the performance of U.S. national communication and navigation assets [6]. Deploying the first known ground-to-space bistatic coherent-scatter radar system, the RAX mission will coordinate a network of megawatt-class ground-based radar observatories with an on-orbit CubeSat radar receiver to yield a unique scattering geometry (Figure 1) for characterizing the climatology and evolution of meter-scale ionospheric structures—features inaccessible to ground-based observation [5]. These globally observed ionospheric irregularities, driven by interaction of naturally occurring strong electric fields and ionospheric plasma gradients, result from a chaotic interplay of solar magnetic and ultraviolet forcing of Earth's upper atmosphere.

The RAX mission will investigate ionospheric irregularities to gain insight into several

**Figure 1** – Schematic drawing of the RAX mission radar geometry. A ground radar transmits radar pulses towards irregularities that are aligned with the Earth’s magnetic field. The irregularities scatter these signals towards space. RAX will receive these signals, process them onboard, and downlink to the science operations center.

candidate causal mechanisms (plasma instabilities), only a few of which have been observed by ground-based research radars. By gauging the global spatial distribution of these ionospheric irregularities and their causal geophysical drivers, the RAX mission will advance the state of *space weather forecast*.

The itemized science objectives of the RAX mission are given by the questions below:

1. What is the altitude distribution of high-latitude ionospheric irregularities as a function of convective electric fields?
2. Which plasma waves are responsible for these irregularities?
3. To what extent are the irregularities field-aligned?

**MISSION CONSTRAINTS**

Design of the RAX mission began in 2008 with several constraints and programmatic requirements that shaped the nature of the project.

**Cubesat Form Factor**

First, all satellites in this NSF program are Cubesats, and therefore RAX must conform to the Cubesat standard [3]. Cal Poly and Stanford University developed the standard, and it simply defines several structural features of the satellite. The mission was allotted a 3U satellite, nominally with a volume of 10x10x30cm and less than 3kg. Thus, the science mission was crafted to utilize this resource-constrained satellite.

**Launch Manifest**

The second constraint (and also an opportunity) was a manifested launch opportunity on a US Air Force Space Test Program launch, STP-26, for the RAX mission. At program inception, the launch date was scheduled for December 2009 and the orbital parameters were a 650 km circular orbit at an inclination of 72 degrees. This resulted in two distinct sub-constraints. Design, built, test, and delivery of the RAX mission had to be done in less than 12 months. Also, at an altitude of 650 km, assessment of deorbit properties was a prime driver for the satellite mass and structural properties. A 25-year deorbit after mission life was achieved by fixing the RAX structure to a typical 3U and keeping the mass less than 3 kg.

**MISSION DESCRIPTION**

The RAX payload receiver design leveraged extensively the SRI design for NSF’s Advanced Modular Incoherent Scatter Radar (AMISR). The RAX spacecraft bus design, in turn, grew out of the University of Michigan’s (UMich) extensive experience with over ten small satellites, including several Cubesat missions. We describe the payload and spacecraft configuration, with focus on the attitude determination and control subsystem (ADCS), position and timing subsystem (PTS), EPS, flight central processing unit (FCPU) subsystem, communication subsystem

(COMMS), and the instrument data processing unit (IDPU).

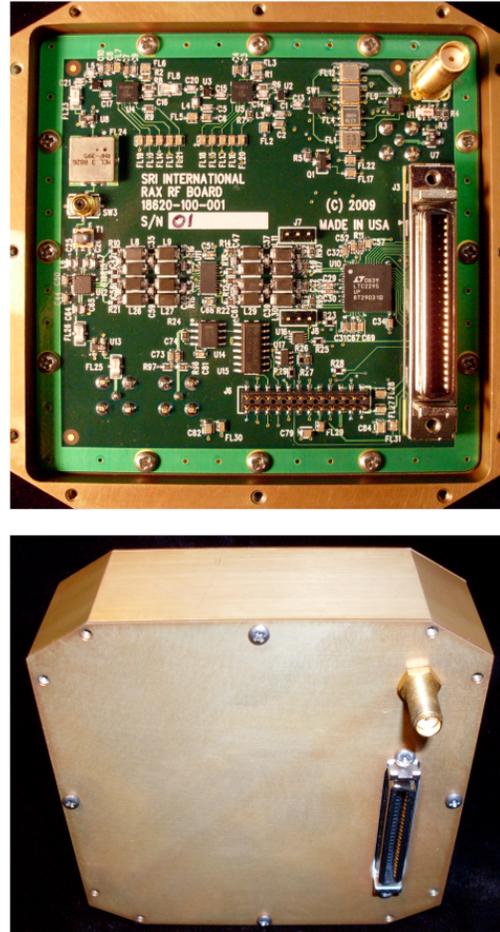

### ***Payload Receiver***

To satisfy science goals, the RAX receiver (Figure 2) tunes and converts the radar echoes scattered off meter-scale ionospheric structures. These signals may be transmitted from any one of five terrestrial radar observatories. Received echoes are digitized at 14-bit resolution with 1 MHz sampling and are time-tagged for subsequent downlink. The receiver, a direct-conversion (homodyne) design using industrial-grade analog components, was employed to improve overall reliability and to minimize susceptibility to radiation and transient energetic particle events. The RAX receiver also exhibits extremely wide RF dynamic range (60 dB), rapid (10  $\mu$ s) overload recovery, minimal power consumption (2.6 W), efficient internal heat dissipation, stable long-term frequency lock, and robust protection from EMI.

In order to certify the SRI payload for integration into the UMich bus, the RAX receiver as a functional subsystem successfully survived a test regime that included accelerated-life RF testing, thermal/vacuum (T/VAC) forcing ( $-40^{\circ}$  to  $50^{\circ}$  C), EMI screening, and vibration exposure per NASA General Environmental Verification Standard. The RAX receiver is currently at TRL 5 as a completed subsystem and demonstrated as operational in a relevant environment with low-vacuum, thermal forcing, and realistic EMI background.

### ***Satellite Description***

The RAX spacecraft bus provides attitude knowledge/control, timing, power, science downlink, and command telemetry in a 3U structure (Figure 3). RAX is compliant with the Cubesat standard except on two points: the center of mass is slight outside the desired center of volume, and the dimensions are

**Figure 2** – The SRI payload receiver to be flown on the RAX satellite.

slightly out of specification but within tolerances of the Cal Poly P-Pod. At 3 kg, RAX is expected to deorbit in 25 years post-mission for orbits up to an altitude of  $\sim 650$  km.

**ADCS.** Mission science goals require that RAX spacecraft attitude be determined to within  $\pm 7^{\circ}$  so that received radar pulse power can be properly calibrated. With known spacecraft position converted to magnetic field on-board, attitude knowledge is provided by a combination of six miniaturized magnetometers, six sun sensors, and an inertial measurement unit. The ADCS attitude knowledge precision is  $5^{\circ}$ . Attitude control,

provided by a longitudinal permanent magnet and two orthogonal hysteresis rods, provides 7° authority with minimal oscillation and is judged sufficient to accomplish RAX science objectives. The ADCS is currently at TRL 5.

**PTS.** The RAX PTS provides spacecraft absolute position to the ADCS. The PTS also provides 40 m/s accurate spacecraft velocity and 1 μs accurate timing (relative to GPS pulse-per-second synchronization) to the RAX payload receiver as mandated by science requirements. These requirements are met with a combination of periodic orbital element uplink, an onboard GPS receiver and associated antenna, a real-time clock, and synchronization data encoded onto the ground radar pulse pattern. The PTS is at TRL 6.

**EPS.** RAX EPS comprises solar panels, a battery system, and associated regulation and conditioning circuitry. The battery system is implemented with 7.4V, 4.4 A-h Li- Ion cells housed in a PCB-backed aluminum frame. The EPS provides a controller for maximizing energy throughput from solar panels to battery (44 W max but with an on-orbit average expected at 6W) and a bus regulation system with sufficient margin to ensure regulated 3.3V and 5V output for all mission phases. The load set point of the EPS controller is statically set to extract maximum power output from the panels based on preflight orbit simulations. Internal sensors measure voltage, current, and temperature within the battery, solar panels, and bus controller. The EPS was created by UMich to better enhance safety and reliability over off the shelf solutions. The EPS has survived vibration and T/VAC testing. The EPS is currently at TRL 5.

**FCPU.** The RAX flight computer, responsible for all phases of subsystem and payload command and control, is implemented with an UMich-built flight computer using an MSP430 from TI. An off the shelf real-time operating system is used with RAX-specific

**Figure 3** – The RAX satellite fully integrated.

low level drivers and application code developed at UMich and SRI to provide the necessary mode flexibility required by RAX throughout all mission phases: uplink command reception, science data acquisition and buffering, science data processing mode, and science downlink mode. The MSP430 was selected due to its flight heritage, relatively low cost, and access to previously developed processor compatible code. The FCPU is judged to be at TRL 5.

**COMMS.** The FCPU board was designed to host an S-band transceiver, which will be used for 100 kbps science data downlink at 2.4 GHz via a small UMich-designed patch antenna. RAX also implements an UHF transceiver as an uplink command receiver

and as a redundant downlink science transmitter. The UHF transceiver will operate in the amateur band and will share the quad turnstile antenna used for the RAX payload radar receiver. The COMMS is currently at TRL 5.

**IDPU.** The IDPU is a Linux-based processor running at 500 MH that post-processes onboard radar data. For each experiment, 1.5 GB of data is generated, and that is well beyond RAX's downlink capabilities. Various science modes that utilize GPS-based time tagging, radar encoded time synchronization, and satellite motion parameters are used to process radar data and reduce downlink requirements.

### **METHODOLOGIES**

Given the schedule, form-factor and cost constraints present during mission inauguration, the RAX team adopted several design strategies and approaches to accommodate the constraints.

#### ***University-Class Mission***

The RAX mission is a university-class mission as described by Swartwout [4]. NSF's combination of science and educational goals enabled our team to consist primary of graduate and undergraduate students. Over fifty students have been involved from the University of Michigan and other schools.

Student effort is supported by intense PI involvement and oversight. PI's have an active role in design, building and testing of RAX. This provides the proper structure and motivation to harness student capabilities and energies, while providing many n-situ, immersive educational opportunities that go well beyond typical class room interactions.

In addition, periodic consultants were integrated into the team to provide specialized expertise when needed. This included design support on the EPS and radio systems.

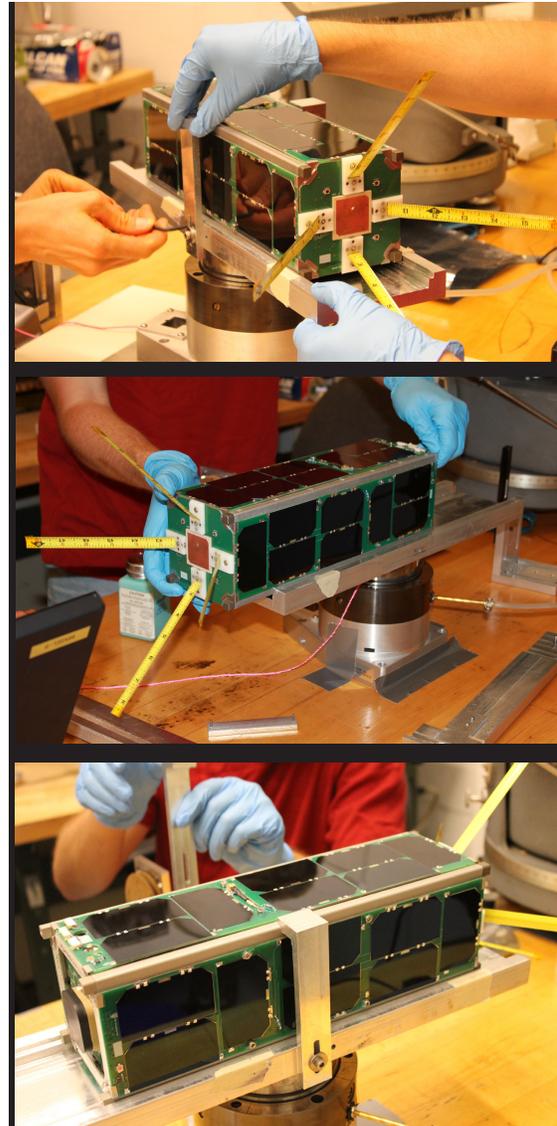

Figure 4 – Inertia and mass property measurement of RAX.

#### ***Continuous Improvement Model***

Given the uncertainty in a launch date, the RAX team developed a method to both meet pending launch-related deadlines as well as take advantage of delays in delivery to improve and enhance mission capabilities. This *continuous improvement model* (CIM) produced several flight ready satellites that were later reworked to enhance functionality and science yield.

As with typical space missions, requirements were developed to satisfy mission goals. A minimum-effort mission was developed to meet these goals that utilized simple attitude control methods and extensive use of off the shelf components for the first launch deadline, December 2009. As the launch slipped, improvements were made that included advanced GPS position and time synchronization. Some technologies did not make it on board due to schedule constraints such as three-axis active attitude control. While it would have enhanced communication and science collection capabilities, it was not required and thus demanifested from the satellite.

## **SUMMARY**

The first RAX satellite, RAX-1, is complete and awaiting a launch on STP-S26, a Minotaur IV launching from Kodiak Island. It is expected to launch late 2010. RAX-1 has passed stringent launch and payload readiness reviews chaired by the US Air Force. RAX-1 will operate in full science collection mode for at least one year pending nominal satellite performance. Beyond the baseline science operation, ad-hoc science experiments will be performed and the satellite will transition to an educational testbed for students.

A second satellite identical to RAX-1 has been built and tested as well. It is storage until a second launch opportunity is available. If a second launch is sufficiently in the future, it will be deintegrated and upgraded to include faster communication and processing capabilities.

The RAX mission offers an excellent opportunity to push the state of the art in science studies while training the next generation of space scientists and engineers. The science products are expected to provide novel insight into space weather processes that have been impossible to measure before with existing technology. Numerous students have

capped their educational experience with RAX mission work and the on orbit flight of RAX is expected to train many additional students as well.

## **ACKNOWLEDGEMENTS**

The RAX Team is grateful to many who have enabled this opportunity. This work was supported by NSF grant ATM-0838054 to SRI International and the University of Michigan. The Michigan Space Grant Consortium provided invaluable support to summer students from several Michigan schools to support RAX. NASA Glenn, Orbital Science Corporation, Aerospace Corporation, and JPL provided testing resources for RAX. We thank Ed Boesiger from Lockheed Martin who supported RAX with a thermal test chamber. We thank our part suppliers and their rapid responses to our urgent requests. Cal Poly has been instrumental in support of our launch integration and testing. And thank you to all the RAX team members who have worked diligently on this mission.
